Research Problem

The increase of fast food establishments and the popularity of fast food consumption among students raise concerns about its potential adverse effects on their health and well-being. Despite growing awareness of the nutritional shortcomings of fast food, there is a lack of comprehensive research examining the specific health consequences experienced by students who frequently consume fast food. Understanding the effects of fast food consumption on students' health is essential for developing targeted interventions and policies to promote healthier dietary behaviors and mitigate the risk of chronic diseases in this vulnerable population. Therefore, the research problem addressed in this study is:

1-"What are the specific health effects of frequent fast food consumption among students?

2-How do these effects vary by age, gender, and dietary habits?"

Research Hypothesis

1.Behavioral Hypotheses:

1.H1: Students who consume fast food more frequently exhibit higher levels of impulsivity and hyperactivity compared to those with lower fast food consumption.

2.Fast food consumption is positively correlated with increased screen time and sedentary behavior among students.

3. Fast food consumption is associated with poorer sleep quality and disrupted sleep patterns among students.

2.Health Hypotheses:

1.: Regular consumption of fast food among students is positively associated with higher body mass index (BMI) and increased risk of obesity.

2.: Fast food consumption is linked to elevated blood pressure, cholesterol levels, and other cardiovascular disease risk factors among students.

3.: Students who frequently consume fast food have poorer overall nutritional status, characterized by inadequate intake of essential nutrients and micronutrients.

Research Significance

iPSC technology has several advantages that has created a new era in stem cell research includes but are not limited to: (1) it overcomes the limitations and challenges associated with ESCs usage. (2) iPSC technology allowed the generation of human-derived cellular models of human diseases that were difficult to be recapitulated using other types of models, such as animal models. This places iPSCs in the forefront as a real human-derived cell model that could help in understanding the molecular mechanisms underlying the pathogenesis of a disease. (3) generating patient specific iPSCs in vitro create a great advantage to screen for drugs and thus help in drug discovery that is specific for each patient, which is a step towards personalized medicine. (4) using iPSCs that are genetically identical to the patient as a replacement therapy for some diseases is a long-term advantage for this technology, which would avoid immune rejection problems associated with using ESCs in regenerative medicine. Collectively, using iPSCs can be a promising approach for applying the concept of personalized medicine. Based on the above-mentioned importance of iPSC and its applications, our project is considered of high significance because it aims to explore a more efficient reprogramming approach would help to generate a high quality iPSCs that could be used in clinical trials and as a potential cure for patients harboring different disease

Research Methodology

As discussed previously, the methodology followed is a kind of descriptive method and this could involve surveys, dietary assessments, medical records review, physical examinations, or biomarker measurements. we will ensure that data collection methods are valid, reliable, and ethically sound.

Results

The results can be in three results

1- Students are not willing to change their food habits

2-The number of students consuming fast food is increasing.

3-Long-Term Health Risks: Habitual consumption of fast food during adolescence can establish unhealthy eating patterns that persist into adulthood, increasing the risk of chronic diseases such as cardiovascular disease, stroke, and certain cancers.

introduction

As students, we would like to focus on the focal issue related to a nutritious issue which can affect our health and behavior.
Hence, food is a very important factor that promotes students' mental and psychological fields.

As we witnessed in the school environment, many students don't pay attention to their health as they put their life at risk.
Healthy students are more likely to attend school regularly and actively engage in learning activities. Chronic health issues or illnesses can lead to frequent absences, which can disrupt learning and hinder academic progress.

As it is discussed students' health is by no means a very crucial part which may affect the academic level as well.
Mental health plays a significant role in students' overall health and academic success. Students who are emotionally resilient, socially connected, and equipped with coping strategies are better able to handle stress, navigate challenges, and maintain a positive outlook on life.

Conclusions and Recommendations

Encouraging Physical Activity: Efforts should be made to encourage regular physical activity among students to counteract the sedentary behavior associated with fast food consumption. Schools can offer opportunities for physical education, sports, and extracurricular activities to promote an active lifestyle.
